1. Summary

USDB is an ERC-20 token on Ethereum mainnet, denominated in US dollars and issued by Blotix Fund LLC. It is the settlement token of the Blotix ecosystem: when a client of the Blotix platform withdraws their balance, Blotix pays the withdrawal in USDB to the client's own Ethereum wallet. The client can hold the tokens, transfer them, or exchange them for USDT on the USDB/USDT Uniswap V3 pool.

The contract is built on OpenZeppelin Contracts 5.6.1 and follows the control model of the major USD tokens: a single issuer (a Safe multisig) can mint and burn, pause transfers and freeze addresses. The contract is not upgradeable, charges no fees, and the issuer role cannot be renounced. Its source code is verified on Etherscan and has been analyzed with Slither; no independent third-party audit has been performed yet.

USDB is a means of payment for Blotix clients, not a product sold to the public. It is not an investment product, no guarantee of price stability is made, and nothing in this document is investment advice.

2. Purpose within the Blotix ecosystem

Blotix operates a protocol for real-world-asset (RWA) tokenization with its own ERC-20 token, BLOTIX. Platform clients hold balances inside the Blotix platform. Historically, withdrawals were paid in BLOTIX, which exposed clients to the volatility and liquidity conditions of that token at the moment of withdrawal.

USDB separates the two functions. BLOTIX remains the ecosystem token; USDB is the unit in which clients are paid. This gives clients a US-dollar-denominated asset that they can use anywhere on Ethereum, and gives Blotix a payment rail whose value does not depend on the BLOTIX market.

Payment flow

Step	Action	Where
1	The client requests a withdrawal of part or all of their balance.	Blotix platform
2	Blotix converts the balance to its US-dollar value and transfers that amount in USDB from its treasury to the client's wallet. If the treasury needs more USDB, the issuer mints it.	Ethereum · issuer Safe / treasury
3	The client holds, transfers, or swaps USDB for USDT on Uniswap V3. The issuer maintains USDT liquidity in the pool in line with the payments made.	Ethereum · Uniswap V3 pool
4	USDB that returns to the issuer may be burned, reducing supply.	Ethereum · issuer Safe

3. Token specification

Parameter	Value
Name / Symbol	USDB / USDB
Standard	ERC-20 with EIP-2612 permit (gasless approvals by signature)
Decimals	6 (same as USDT and USDC)
Network	Ethereum mainnet (chain id 1)
Contract address	0xDAF05C8680A06a5A30A8e3Ffe25062eD4e4D21fB
Deployed	12 September 2026, tx 0xc98efac51aa6894e2962652a1a17cc3a55997c558453daaba0dc1b83e66854fc
Compiler	Solidity 0.8.26, optimizer enabled (200 runs); source verified on Etherscan (exact match)

Initial supply	0 — supply is created by the issuer as payments require
Owner (issuer)	Safe multisig 0xEA3021F4A10a94E80d60bF7Cc1f855312E263846 (Safe 1.4.1)
Upgradeability	None. No proxy; the deployed bytecode is final
Transfer fees	None
ETH handling	The contract does not accept ETH

4. Contract architecture

The contract inherits four audited OpenZeppelin 5.6.1 building blocks and adds a small issuer layer:

Component	Role
ERC20	Standard balances, transfers and allowances.
ERC20Permit	EIP-2612 signed approvals (permit), EIP-712 domain "USDB".
Ownable2Step	Single owner (the issuer). Ownership changes require the new owner to accept, so a typo cannot lose control of the contract.
Pausable	Global pause of transfers, transferFrom and permit.
Issuer layer (USDB)	Fixed 6 decimals; mint/burn; blacklist with destroyBlackFunds; rescueERC20 for tokens sent to the contract by mistake; renounceOwnership overridden to revert.

Behavior matrix

Function	While paused	Sender or recipient blacklisted
transfer / transferFrom	Reverts	Reverts
approve	Allowed	Reverts
permit	Reverts	Reverts
mint (issuer)	Allowed	Reverts if recipient is blacklisted
burn (issuer's own balance)	Allowed	n/a
destroyBlackFunds (issuer)	Allowed	Only on blacklisted addresses

The issuer keeps the ability to mint, burn and destroy blacklisted funds while the token is paused, so that an incident response does not depend on unpausing first.

5. Issuer functions

All functions below are restricted to the contract owner, i.e. the issuer's Safe multisig. Every call is a public on-chain transaction and emits an event.

Function	Purpose	Event
<code>mint(to, amount)</code>	Create new USDB for a payment. Reverts for the zero address, zero amount or a blacklisted recipient.	Mint
<code>burn(amount)</code>	Destroy USDB held by the issuer (redemption).	Burn
<code>pause()</code> / <code>unpause()</code>	Stop and resume all transfers.	Paused / Unpaused
<code>blacklist(account)</code> / <code>unBlacklist(account)</code>	Freeze or unfreeze an address.	Blacklisted / UnBlacklisted
<code>destroyBlackFunds(account)</code>	Burn the full balance of a blacklisted address.	DestroyedBlackFunds
<code>rescueERC20(token, to, amount)</code>	Recover ERC-20 tokens sent to the contract by mistake.	ERC20Rescued
<code>transferOwnership(newOwner)</code> / <code>acceptOwnership()</code>	Two-step change of issuer.	OwnershipTransferStarted / OwnershipTransferred
<code>renounceOwnership()</code>	Disabled — always reverts with <code>RenounceDisabled</code> .	—

6. Issuance, reserves and redemption

Issuance. USDB starts with zero supply. The issuer mints tokens as payments to clients require, from the Safe multisig. There is no maximum supply and no scheduled emission: supply tracks the payments Blotix makes.

Reserves. USDB is supported by USDT (Tether) reserves held by the issuer. When Blotix pays clients in USDB, it supplies USDT liquidity to the USDB/USDT Uniswap V3 pool in line with the payments made, so that clients can exchange their USDB without depending on the issuer's availability. On-chain publication of the reserve address is planned once the treasury is fully migrated to the multisig; until then reserves are held by the issuer and are not publicly attested.

Redemption. Clients redeem through the market: the USDB/USDT pool on Uniswap V3 (0.01% fee tier, pool `0x74bf3e066e624b848c178407f2f4cbba6205be2e`). USDB that returns to the issuer may be burned. The issuer does not operate a direct redemption desk for the public.

USDB is denominated in US dollars, but no guarantee of price stability is made. The price on Uniswap depends on the liquidity available in the pool at a given moment and on market conditions.

7. Governance and key management

The only privileged role in the contract is the owner, held by a Safe multisig (Safe 1.4.1) at 0xE3021F4A10a94E80d60bF7Cc1f855312E263846. Every issuer action is a Safe transaction, visible on-chain together with the signers who approved it.

- **Signers.** The Safe is being expanded from its launch configuration to a 2-of-3 threshold with an offline backup key, so that no single key can act alone and the loss of one key does not lock the issuer role.
- **Ownership changes** use OpenZeppelin's two-step pattern: a transfer must be accepted by the new owner before it takes effect.
- **No renounce.** The contract can never be left without an issuer.
- **Treasury.** Circulating USDB not yet paid to clients and the pool liquidity position are being consolidated under the multisig as part of the roadmap.

8. Security

- **Verified source.** The exact single-file source is published and verified on Etherscan, so the deployed bytecode can be checked against it by anyone.
- **Audited foundations.** All token logic comes from OpenZeppelin Contracts 5.6.1; the USDB-specific layer is about 150 lines of straightforward access control.
- **Static analysis.** Slither (Trail of Bits, 102 detectors) was run on the verified source with the deployment compiler settings. No High- or Medium-impact finding exists in the USDB contract; every High/Medium result is located in unmodified OpenZeppelin library code (`Math.mulDiv`, `Math.invMod`) that is not reachable from USDB and corresponds to documented false positives. The only USDB-specific result is a cosmetic naming note: the owner parameter of the standard EIP-2612 permit signature shadows the `owner()` getter. The full report is published in the repository.
- **Immutability.** No proxy, no upgrade path, no self-destruct.
- **Independent audit.** Not yet performed; planned as part of Phase 3 of the roadmap.

9. Compliance controls

Like USDT and USDC, USDB gives the issuer the ability to pause the token and to freeze specific addresses (`blacklist`) and destroy their balance (`destroyBlackFunds`). These controls exist to respond to legal orders, sanctions requirements and security incidents such as stolen funds. They are executed only through the Safe multisig, each use emits an event and is permanently visible on-chain.

10. Risks and disclaimers

- **Issuer risk.** The value of USDB depends on the issuer maintaining reserves and pool liquidity. USDB is not a bank deposit and is not insured.
- **Liquidity and price risk.** The market price on Uniswap can deviate from 1 USD, in particular when the pool holds little USDT relative to the amount being sold.
- **Smart-contract risk.** The contract is verified and analyzed but has not been independently audited. Ethereum and Uniswap carry their own protocol risks.
- **Issuer controls.** The issuer can pause transfers and freeze addresses. Holders should be aware that these controls exist.
- **Regulatory risk.** The treatment of US-dollar-denominated tokens varies by jurisdiction and may change. USDB is issued only to Blotix clients as payment and is not offered to the public.
- **Symbol collision.** Other unrelated tokens on other networks use the symbol USDB. Always verify the contract address: 0xDAF05C8680A06a5A30A8e3Ffe25062eD4e4D21fB on Ethereum mainnet.

This document describes the technical design and operating model of USDB. It is not an offer, solicitation or recommendation to buy or sell any asset and does not constitute legal, tax or investment advice.
